MV CYANO data are generated from a bbe Moldaenke Fluoroprobe instrument. This instrument is a fluorometer, which measures the biomass (quantity) of microscopic plants by detecting the fluorescence produced in response to different wavelengths of light. The amount of fluorescence is directly related to the concentration of plant pigments in the sample. Different types of microscopic aquatic plants, called phytoplankton, utilize different pigments, which allows the fluorometer to differentiate and quantify different phytoplankton groups. The Fluoroprobe measures the concentration of cyanobacteria in micrograms per liter ( $\mu\text{g/L}$ ) and estimates the number of cells per milliliter (cells/mL). The MV CYANO color designations are based on the  $\mu\text{g/L}$  measurement. The total amount of plant pigments in the water sample corresponds to the amount of chlorophyll, measured in  $\mu\text{g/L}$ . The concentration of chlorophyll is a measurement of the phytoplankton biomass in the sample. Salinity and water temperature, measured at the time of sample collection, are factors that can influence the growth rate of cyanobacteria and other types of phytoplankton. The MV CYANO color determination (see color-chart above) corresponds to the risk level determined by the local Board of Health agencies based on the concentration of cyanobacteria and other environmental factors. The MV CYANO risk matrix is reviewed annually and updated as needed in order to stay current with health standards and scientific studies.
